Report Manifest

Item	Description
Client	Cakepie
Target	Cakepie Contracts

Version History

Version	Date	Description
1.0	Dec 10, 2023	First Release
1.1	Dec 29, 2023	Additional Comments

About BlockSec BlockSec focuses on the security of the blockchain ecosystem and collaborates with leading DeFi projects to secure their products. BlockSec is founded by top-notch security researchers and experienced experts from both academia and industry. They have published multiple blockchain security papers in prestigious conferences, reported several zero-day attacks of DeFi applications, and successfully protected digital assets that are worth more than 5 million dollars by blocking multiple attacks. They can be reached at Email, Twitter and Medium.

Chapter 1 Introduction

1.1 About Target Contracts

Information	Description
Туре	Smart Contract
Language	Solidity
Approach	Semi-automatic and manual verification

The target of this audit is the code repository of Cakepie Contracts¹ of Cakepie. Cakepie is a yield optimization protocol built upon PancakeSwap. It enables users to manage PancakeSwap V2/V3 positions and claim rewards. CAKE holders can convert their CAKE token or locked CAKE positions from PancakeSwap on Cakepie. In addition, Cakepie grants users governance rights. Users with voting powers can vote in Cakepie and votes will be cast to Pancake's GaugeVoting. Cakepie also incorporates a bribe market where users can add bribes that are distributed to active voters.

Please note that this audit only covers the following contracts:

- PancakeV3Helper.sol
- PancakeV2Helper.sol
- PancakeAMLHelper.sol
- PancakeStakingBNBChain.sol
- mCakeConvertorBNBChain.sol
- mCakeConvertorSideChain.sol
- PancakeStakingBaseUpg.sol
- mCakeConvertorBaseUpg.sol
- DustRefunder.sol
- Enumerable.sol
- CakepieReceiptToken.sol
- Cakepie.sol²
- CakepieBribeManager.sol
- CakepieBribeDistributor.sol
- PancakeVoteManager.sol
- RewardDistributor.sol
- BaseRewardPoolV3.sol

The auditing process is iterative. Specifically, we would audit the commits that fix the discovered issues. If there are new issues, we will continue this process. The commit SHA values during the audit are shown in the following table. Our audit report is responsible for the code in the initial version (Version 1), as well as new code (in the following versions) to fix issues in the audit report.

¹https://github.com/magpiexyz/cakepie_contract

²In the commit f31c87aaa0f8143f0c9fd9581f7b62f3873330ea, the auditors are requested to audit a new version of this file, which is moved to path contracts/cakepie/crosschain/Cakepie.sol and changed to a different implementation of the Cakepie token. The auditors have reviewed the file in the specified commit and found no issue.

Project	Version	Commit Hash
Cakenie Contracts	Version 1	3abfc8d14d473eb53947963c0fcbdc4af2653eaa
Cakepie Contracts	Version 2	da2b39eb120affdca2cc6b930efd6312bedea5a6

1.2 Disclaimer

This audit report does not constitute investment advice or a personal recommendation. It does not consider, and should not be interpreted as considering or having any bearing on, the potential economics of a token, token sale or any other product, service or other asset. Any entity should not rely on this report in any way, including for the purpose of making any decisions to buy or sell any token, product, service or other asset.

This audit report is not an endorsement of any particular project or team, and the report does not guarantee the security of any particular project. This audit does not give any warranties on discovering all security issues of the smart contracts, i.e., the evaluation result does not guarantee the nonexistence of any further findings of security issues. As one audit cannot be considered comprehensive, we always recommend proceeding with independent audits and a public bug bounty program to ensure the security of smart contracts.

The scope of this audit is limited to the code mentioned in Section 1.1. Unless explicitly specified, the security of the language itself (e.g., the solidity language), the underlying compiling toolchain and the computing infrastructure are out of the scope.

1.3 Procedure of Auditing

We perform the audit according to the following procedure.

- **Vulnerability Detection** We first scan smart contracts with automatic code analyzers, and then manually verify (reject or confirm) the issues reported by them.
- Semantic Analysis We study the business logic of smart contracts and conduct further investigation on the possible vulnerabilities using an automatic fuzzing tool (developed by our research team).
 We also manually analyze possible attack scenarios with independent auditors to cross-check the result.
- **Recommendation** We provide some useful advice to developers from the perspective of good programming practice, including gas optimization, code style, and etc.

We show the main concrete checkpoints in the following.

1.3.1 Software Security

- * Reentrancy
- * DoS
- * Access control
- * Data handling and data flow
- * Exception handling
- * Untrusted external call and control flow
- * Initialization consistency
- * Events operation

- * Error-prone randomness
- * Improper use of the proxy system

1.3.2 DeFi Security

- * Semantic consistency
- * Functionality consistency
- * Permission management
- * Business logic
- * Token operation
- * Emergency mechanism
- * Oracle security
- * Whitelist and blacklist
- * Economic impact
- * Batch transfer

1.3.3 NFT Security

- * Duplicated item
- * Verification of the token receiver
- * Off-chain metadata security

1.3.4 Additional Recommendation

- * Gas optimization
- * Code quality and style

Ý

Note The previous checkpoints are the main ones. We may use more checkpoints during the auditing process according to the functionality of the project.

1.4 Security Model

To evaluate the risk, we follow the standards or suggestions that are widely adopted by both industry and academy, including OWASP Risk Rating Methodology ³ and Common Weakness Enumeration ⁴. The overall *severity* of the risk is determined by *likelihood* and *impact*. Specifically, likelihood is used to estimate how likely a particular vulnerability can be uncovered and exploited by an attacker, while impact is used to measure the consequences of a successful exploit.

In this report, both likelihood and impact are categorized into two ratings, i.e., *high* and *low* respectively, and their combinations are shown in Table 1.1.

Accordingly, the severity measured in this report are classified into three categories: **High**, **Medium**, **Low**. For the sake of completeness, **Undetermined** is also used to cover circumstances when the risk cannot be well determined.

Furthermore, the status of a discovered item will fall into one of the following four categories:

³https://owasp.org/www-community/OWASP_Risk_Rating_Methodology

⁴https://cwe.mitre.org/

- **Undetermined** No response yet.
- **Acknowledged** The item has been received by the client, but not confirmed yet.
- **Confirmed** The item has been recognized by the client, but not fixed yet.
- Fixed The item has been confirmed and fixed by the client.

Chapter 2 Findings

In total, we find **six** potential issues. Besides, we also have **five** recommendations and **one** note.

- Medium Risk: 3
- Low Risk: 3
- Recommendation: 5
- Note: 1

ID	Severity	Description	Category	Status
1	Medium	Uninitialized state variables	Software Security	Fixed
2	Medium	Incorrect interface used for CakepieBribeManager	Software Security	Fixed
3	Medium	Potential DoS to native token transfer due to insufficient gas	Software Security	Fixed
4	Low	Potential inconsistent pool identifier	Software Security	Fixed
5	Low	Potential inconsistent token pairs	DeFi Security	Fixed
6	Low	Insufficient check on the Pancakeswap pool	DeFi Security	Fixed
7	-	Implement usages for unused isActive flags	Recommendation	Acknowledged
8	-	Add sanity checks before setting parameters	Recommendation	Fixed
9	-	Remove unused logic	Recommendation	Fixed
10	-	Fix typo in CakepieBribeRewardDistributor	Recommendation	Fixed
11	-	Remove unused payable attribute	Recommendation	Fixed
12	-	Centralization risk	Note	-

The details are provided in the following sections.

2.1 Software Security

2.1.1 Uninitialized state variables

Severity Medium

Status Fixed in Version 2

Introduced by Version 1

Description In the following contracts, there are several state variables that cannot be set through constructors or privileged functions:

- The CKPRatio variable of the RewardDistributor contract, which specifies the distribution ratio of Cakepie rewards.
- The gaugeVoting variable of the PancakeStakingBNBChain contract, which specifies the address for the GaugeVoting contract from PancakeSwap.
- The voter variable of the PancakeVoteManager contract, which specifies the address for the GaugeVoting contract from PancakeSwap.

Impact The Cakepie rewards cannot be distributed and the voting cannot be cast on the GaugeVoting contract.

Suggestion Configure the uninitialized state variables accordingly.

2.1.2 Incorrect interface used for CakepieBribeManager

Severity Medium
Status Fixed in Version 2

Introduced by Version 1

Description The PancakeVoteManager contract attempts to invoke the exactCurrentEpoch function in the CakepieBribeManager contract (Line 284). However, there is no such interface in the target CakepieBribeManager contract.

278	<pre>function _afterVoteUpdate(</pre>
279	address _user,
280	address _pool,
281	uint256 _pid,
282	int256 _weight
283) internal virtual {
284	<pre>uint256 epoch = ICakepieBribeManager(bribeManager).exactCurrentEpoch();</pre>
285	<pre>emit Voted(epoch, _user, _pool, _pid, _weight);</pre>
286	}

Listing 2.1: PancakeVoteManager.sol

Impact Users cannot vote due to the revert in the <u>_afterVoteUpdate</u> function.

Suggestion Revise the incorrect interface accordingly.

2.1.3 Potential DoS to native token transfer due to insufficient gas

Severity Medium

Status Fixed in Version 2

Introduced by Version 1

Description The <u>_refundETH</u> function in the <u>DustRefunder</u> contract utilizes <u>send</u> to transfer native tokens. However, this can fail if the recipient is a proxy contract whose fallback function consumes significant gas, causing a DoS.

```
34 function _refundETH(address payable _dustTo, uint256 _refundAmt) internal {
35     if (_refundAmt > 0) {
36         bool success = _dustTo.send(_refundAmt);
37         require(success, "ETH transfer failed");
38     }
39 }
```

Listing 2.2: DustRefunder.sol

Impact Contract users using a proxy cannot increase liquidity due to the revert in the <u>_refundETH</u> function.

Suggestion Revise the code logic accordingly.

2.1.4 Potential inconsistent pool identifier

Severi	ty Low
Status	Fixed in Version 2
Introd	uced by Version 1
Descri	ption In the CakepieBribeManager contract, a pool identifier consists of an epoch and a pid.
317 318 319	<pre>function _getPoolIdentifier(uint256 _epoch, uint256 _pid) internal pure returns (bytes32) { return keccak256(abi.encodePacked(_epoch, _pid)); }</pre>

Listing 2.3: CakepieBribeManager.sol

However, this contract allows the admin to force reset a pools pid, introducing potential data inconsistency issues. Specifically, the bribe information is indexed based on these pool identifiers. If a pools pid is reset improperly, it can break this index and cause unexpected behavior.

```
392 function forceSetMarketPID(address _pool, uint256 _newPid) external onlyOwner {
393     poolToPid[_pool] = _newPid;
394 }
```

Listing 2.4: CakepieBribeManager.sol

Impact N/A

Suggestion Revise the code logic accordingly.

2.2 DeFi Security

2.2.1 Potential inconsistent token pairs

Severity Low

Status Fixed in Version 2

Introduced by Version 1

Description In the PancakeStakingBaseUpg contract, the increaseLiquidityV3For function assumes that token1 is the native token when a pool info's isNative field is set to true. However, for token pairs with the native token as token0, this assumption is violated. In such cases, the passed token1 will no longer be the native token, causing the liquidity operation to fail.

The same issue also exists in the DustRefunder contract. It assumes only _token1 can be the native token.

219	<pre>function increaseLiquidityV3For(</pre>
220	address _for,
221	address _v3Pool,
222	IMasterChefV3.IncreaseLiquidityParams calldata params
223) external payable nonReentrant whenNotPaused _onlyPoolHelper(pancakeV3Helper) {
224	<pre>Pool storage poolInfo = pools[_v3Pool];</pre>
225	<pre>address token0 = IPancakeV3PoolImmutables(poolInfo.poolAddress).token0();</pre>
226	<pre>address token1 = IPancakeV3PoolImmutables(poolInfo.poolAddress).token1();</pre>
227	

```
228
          (uint256 balBeforeToken0, uint256 balBeforeToken1) = _checkTokenBalances(token0, token1);
229
230
          IERC20(token0).safeTransferFrom(_for, address(this), params.amount0Desired);
231
          IERC20(token0).safeIncreaseAllowance(address(masterChefV3), params.amount0Desired);
232
233
          if (poolInfo.isNative) {
234
              balBeforeToken1 = address(this).balance - msg.value;
235
              masterChefV3.increaseLiquidity{ value: msg.value }(params);
236
          } else {
              IERC20(token1).safeTransferFrom(_for, address(this), params.amount1Desired);
237
238
              IERC20(token1).safeIncreaseAllowance(address(masterChefV3), params.amount1Desired);
239
240
              masterChefV3.increaseLiquidity(params);
241
          }
242
243
          refundOrTransfer(token0, token1, _for, poolInfo.isNative, balBeforeToken0, balBeforeToken1)
               ;
244
      }
```

Listing 2.5: PancakeStakingBaseUpg.sol

10	<pre>function refundOrTransfer(</pre>
11	address _token0,
12	address _token1,
13	address _dustTo,
14	bool _isNative,
15	<pre>uint256 _balBeforeToken0,</pre>
16	uint256 _balBeforeToken1
17) internal {
18	<pre>uint256 dustToken0Amt = IERC20(_token0).balanceOf(address(this))balBeforeToken0;</pre>
19	<pre>if (dustTokenOAmt > 0) {</pre>
20	<pre>IERC20(_token0).safeTransfer(_dustTo, dustToken0Amt);</pre>
21	}
22	<pre>uint256 dustToken1Amt;</pre>
23	<pre>if (_isNative) {</pre>
24	<pre>dustToken1Amt = address(this).balancebalBeforeToken1;</pre>
25	_refundETH(payable(_dustTo), dustToken1Amt);
26	<pre>} else {</pre>
27	<pre>dustToken1Amt = IERC20(_token1).balanceOf(address(this))balBeforeToken1;</pre>
28	<pre>if (dustToken1Amt > 0) {</pre>
29	<pre>IERC20(_token1).safeTransfer(_dustTo, dustToken1Amt);</pre>
30	}
31	}
32	}

Listing 2.6: DustRefunder.sol

Impact The liquidity cannot be added to token pairs with the native token as token0.

Suggestion Revise the code logic accordingly.

2.2.2 Insufficient check on the Pancakeswap pool

Severity Low

Status Fixed in Version 2

Introduced by Version 1

Description In the PancakeV3Helper contract, the _checkForValidPool function verifies that token0 and token1 of the position match the pool before position operations. However, this check may be inadequate as the same token pair can correspond to multiple pools on PancakeSwap. According to PancakeSwap, a pool is uniquely identified by token0, token1, and fee.

The code logic should not be affected, since the contract interacts with the correct pool. However, it may lead to potential security issues if the event emitted is used off-chain.

```
193
       function _checkForValidPool(
194
          address _for,
195
          address _pool,
196
          uint256 _tokenId,
197
          bool _isStore
       ) internal {
198
199
           (
200
              address token0,
201
              address token1,
202
              int24 tickLower,
203
              int24 tickUpper,
204
              uint128 liquidity,
205
              uint256 feeGrowthInside0LastX128,
206
              uint256 feeGrowthInside1LastX128
207
          ) = getCurrentPosition(_tokenId);
208
209
          address token0Pool = IPancakeV3PoolImmutables(_pool).token0();
210
          address token1Pool = IPancakeV3PoolImmutables(_pool).token1();
211
212
          if (token0Pool != token0 || token1Pool != token1) revert InvalidPool();
213
214
          if (_isStore) {
215
              userPositionInfos[_tokenId] = Position({
216
                  poolAddress: _pool,
217
                  tokenId: _tokenId,
218
                  token0: token0,
219
                  token1: token1,
220
                  tickLower: tickLower,
221
                  tickUpper: tickUpper,
222
                  liquidity: liquidity,
223
                  feeGrowthInside0LastX128: feeGrowthInside0LastX128,
                  feeGrowthInside1LastX128: feeGrowthInside1LastX128
224
225
              });
226
227
              addToken(_for, _tokenId);
228
          }
229
       }
```

Listing 2.7: PancakeV3Helper.sol

Impact N/A

Suggestion Add the check on fee for the pool.

2.3 Additional Recommendation

2.3.1 Implement usages for unused isActive flags

Status Acknowledged

Introduced by Version 1

Description In the following contracts, there are *isActive* flags used to indicate whether a pool or other identity is activated or enabled, but are rarely checked:

- 1. In contract PancakeStakingBaseUpg, the isActive flag for the pools is not checked when harvesting rewards for V3 pools.
- 2. In contract PancakeVoteManager, the isActive flag for pools is set but not checked anywhere.
- 3. In contract RewardDistributor, the isActive flag for whether the fee is enabled is only set but not checked anywhere.

Impact N/A

Suggestion Implement usages for those flags.

2.3.2 Add sanity checks before setting parameters

Status Fixed in Version 2

Introduced by Version 1

Description The following functions set parameters for the contract, but no proper sanity check is implemented:

- 1. The function pushVotingEpoch in contract CakepieBribeManager does not check whether the new epochStartTime is chronologically arranged. And so as forcePushEpoch.
- 2. The function setFeeRatio should check the upper limit (DENOMINATOR, which is 10000) of the feeRatio. Likewise, the forcePushEpoch function should conduct sanity checks about the epoch time.

Impact Missing sanity check may allow misconfiguration.

Suggestion Add sanity checks accordingly.

2.3.3 Remove unused logic

Status Fixed in Version 2

Introduced by Version 1

Description In the following contracts, there are redundant logic or functions that can be removed to reduce code size and gas usage.

1. In contract PancakeStakingBaseUpg, the _onlyAllowedOperator modifier is unused. Besides, the require statement in this modifier is incorrect.

167	<pre>modifier _onlyAllowedOperator() {</pre>
168	<pre>if (allowedOperator[msg.sender]) revert OnlyAllowedOperator();</pre>
169	_;
170	}

Listing 2.8: PancakeStakingBaseUpg.sol

- 2. In contract CakepieBribeManager, the pushBribingEpoch function and currentBribingEpoch state variable is not used.
- 3. In contract PancakeVoteManager, the functions getUserVoteForMarketsInVlCakepie and getUserVoteForPoolsInVlCakepie are exactly the same.

Impact N/A.

Suggestion Remove the unused logic.

2.3.4 Fix typo in CakepieBribeRewardDistributor

Status Fixed in Version 2

Introduced by Version 1

Description There is a typo in function emergencyWithdraw of contract CakepieBribeRewardDistributor. The bribeManager should be NATIVE.

```
253 function emergencyWithdraw(address _token, address _receiver) external onlyOwner {
254    if (_token == bribeManager) {
255        address payable recipient = payable(_receiver);
256        recipient.transfer(address(this).balance);
257    } else {
258        IERC20(_token).safeTransfer(_receiver, IERC20(_token).balanceOf(address(this)));
259    }
260}
```

Listing 2.9: CakepieBribeRewardDistributor.sol

Impact N/A.

Suggestion Fix the typo accordingly.

2.3.5 Remove unused payable attribute

Status Fixed in Version 2

Introduced by Version 1

Description In contract mCakeConvertorBNBChain, the function lockAllCake does not need the payable attribute. Removing this attribute prevents callers from mistakenly transferring native tokens to this contract.

Impact N/A.

Suggestion Remove the payable attribute for this function.

2.4 Note

2.4.1 Centralization risk

Description In the Cakepie contracts, there are privileged functions that can cause severe consequences when misused by the project maintainers.

1. In contract CakepieBribeRewardDistributor, the function emergencyWithdraw can withdraw any token from the contract.

- 2. In contract mCakeConvertorBNBChain, the mintFor function can arbitrarily mint mCake token to any account. There is no contract to call this function, so it is assumed that an operator EOA calls this function.
- 3. In contract BaseRewardPoolV3, the function emergencyWithdraw can withdraw any token from the contract. Besides, the function only allows calls from MasterCakepie, but the contract does not seem to implement this function.
- 4. In contract CakepieBribeManager, the function manualClaimFees effectively withdraw any token from the contract, instead of only withdrawing the unclaimed fees stored in the unCollectedFee state variable.
- 5. In contract CakepieBribeRewardDistributor, rewards are distributed to the users by verifying the merkle proofs submitted and the merkle roots stored in the contract. The operator of the contract can update the merkle roots so that users may be unable to claim their rewards if the roots are reset mistakenly.

Feedback from the Project

- 1. Yes, we want to withdraw all tokens in the contract if we got any emergency situation, this is the onlyOwner function we only can call it through the multiSig account.
- 2. mintFor should be called by pancakeStaking, since in the future, if someone delegates to pancakeStaking, mCake should be minted for the delegator.
- 3. Intended for now, not adding on MasterCakepie unless we really need it when some reward stuck in rewarder.
- 4. In our implementation, only fee might leave in the manager contract if collector not set, reward will be transferred to the distributor directly.
- 5. When rolling merkle tree, off-chain logic does reserve the unclaimed rewards for users, so user won't lose whatever unclaimed.
